Outline

- ❑ Concept of identity
- ❑ Principal in computer systems
- ❑ Identity defined by functions
 - Files and objects
 - Users, groups, and roles
- ❑ Identity for certificates: Certificates and names

Identity

- ❑ *Identity* is simply a computer's representation of an *entity*
- ❑ Principal
 - A *principal* is a unique *entity*.
 - An *identity* specifies a *principal*
- ❑ Authentication
 - Authentication binds a principal to a presentation of identity internal to the system
 - All decisions of access and resource allocation assume that the binding is correct

Purposes of Identities

□ Accountability

- Requires an identity that tracks principals so that the principal taking actions can be unambiguously identified
- Logging and auditing
 - In most systems, logged identity maps to a user account, to a group or to a role

□ Access control

- Requires an identity to determine a specific access (or type of access) should be allowed
 - In most systems, access rights are on the identity of the principal executing process

Principal

- ❑ Principal: a unique entity
- ❑ Identity: specifies a principal
- ❑ Authentication: binding of a principal to a representation of identity internal to the system
 - All access, resource allocation decisions assume binding is correct

Purposes of Principals

□ Accountability

- Tracks principals across actions and changes of other principals
- Any actions taken by the principals can then be unambiguously identified
- Tied to logging and auditing

□ Access control

- Allow or disallow a specific access or a type of access
- Most systems adopt the *process* model
 - A process executed by a user has a subset of the user's rights where the user is presented by an identity

Identity in Computer Systems

- ❑ One would state,
 - User *Alice* can read *Bob's* files
 - Subject: Alice
 - Object: Bob's files
- ❑ Both subjects and objects require identities
- ❑ Be aware of the complexity
 - Multiple names for one thing in different contexts and environments

Files and Objects

- ❑ Identity depends on system containing object
- ❑ Different names for one object
 - Human use
 - ❑ e.g., file name
 - Process use
 - ❑ e.g., file descriptor or handle
 - Kernel use
 - ❑ e.g., file allocation table entry, *inode*

Multiple Names for an Object

- ❑ Different names for one context
 - Human: aliases, relative vs. absolute path names
 - Kernel: deleting a file identified by name can mean two things:
 - ❑ Delete the object that the name identifies
 - ❑ Delete the name given, and do not delete actual object until all names have been deleted
- ❑ Semantics of names may differ
 - Example: one file may have multiple names
 - ❑ On some systems, “deleting a file” is to mean removing the given file name; while on the others, it is to mean to remove the name and the file object.

Example: Files in Linux/Unix

□ 4 different types of file names

1. *inode*
2. File descriptor
3. File names: absolute path names
4. File names: relative path names

inode

- ❑ uniquely identifies a file
- ❑ contains file attribute information, e.g., access control permission and owner information
- ❑ identifies the specific disk blocks that contains the file's data

File Descriptor

- ❑ Abstracts *inode* into a presentation that a process can read from, write to, and so forth
 - i.e., Processes read and write files using a file descriptor
- ❑ Interpretation of Linux/UNIX file descriptor
 - Refers to a specific inode
 - Refers to same inode from creation to deallocation
 - File descriptor cannot rebound to a different file

File Names

- ❑ Identity files by describing their positions in the file hierarchy
- ❑ Absolute path names
 - Describe the locations of files with respect to the root of the Linux/UNIX file hierarchy
- ❑ Relative path names
 - Describe the locations of files with respect to the directory in which the current process is executing
- ❑ Processes and users can use file names to identify files

File Names and inode

- ❑ Interpretation of Linux/UNIX file name
 - Kernel maps name into an *inode* using iterative procedure
 - Same name can refer to different objects at different times without being deallocated
 - ❑ Causes race conditions

Example: Different Systems

- ❑ Object name must encode location or pointer to location
 - rsh, ssh style: host:object
 - URLs: protocol://host/object
 - ❑ <http://www.vsu.edu/academics/registrar/final-exam-schedule.php>
 - ❑ where
 - protocol: http
 - host: www.vsu.edu
 - object: /academics/registrar/final-exam-schedule.php
 - Need not to name actual object
 - ❑ rsh, ssh style may name pointer (link) to actual object
 - ❑ URL may forward to another host

Users

- ❑ One would state,
 - User *Alice* can read *Bob's* files
 - Subject: Alice
 - Object: Bob's files
- ❑ *Identity* tied to a single *entity*
- ❑ Exact representation tied to system
- ❑ Often as identities of principals executing processes

Example: Linux/Unix systems

- ❑ Login name: used to log in to system
 - Logging usually uses this name
- ❑ User identification number (UID): unique integer assigned to user
 - Kernel uses UID to identify users
 - ❑ e.g., the superuser is any user whose UID is 0 regardless of that user's login name
 - One UID per login name, but multiple login names may have a common UID

Multiple Identities for Users in Linux/Unix Systems

- ❑ Real UID: user identity at login, but *changeable*
 - see `setreuid(2)`
- ❑ Effective UID: user identity used for access control
 - `setuid` programs changes effective UID, see `setuid(2)`
- ❑ Saved UID: UID before last change of UID
 - Used to implement least privilege
 - Work with privileges, drop them, reclaim them later
- ❑ Audit/Login UID: user identity used to track original UID
 - *Cannot be altered*; used to tie actions to login identity

Further Reading

Groups and Roles

- The “*entity*” may be a *set of entities* referred to by a single *identifier*
 - Members of the set must be distinguishable
 - The set may have an identity separate from any its members

Groups

- ❑ Used to share access privileges
 - Principals often need to share access to file
 - e.g., all students have access to “StudentActivityPlan.txt”
 - Most systems allow principals to be grouped into sets called *groups*
- ❑ First model: alias for set of principals
 - Processes assigned to groups
 - Processes stay in those groups for their lifetime
- ❑ Second model: principals can change groups
 - Rights due to old group discarded; rights due to new group added

Roles

- ❑ Group with membership tied to function
 - Rights given are consistent with rights needed to perform function
- ❑ Uses second model of groups
- ❑ Example: DG/UX
 - User *root* does not have administration functionality
 - System administrator privileges are in *sysadmin* role
 - Network administration privileges are in *netadmin* role
 - Users can assume either role as needed

Naming and Certificates

- ❑ Certificates as a mechanism for binding cryptographic keys to identifiers
 - Certificates issued to a principal
 - ❑ Principal uniquely identified to avoid confusion
 - ❑ An identifier corresponds to a principal
- ❑ Problem: names may be ambiguous
 - Does the name “Matt Bishop” refer to:
 - ❑ The author of the textbook?
 - ❑ A programmer in Australia?
 - ❑ A stock car driver in Muncie, Indiana?
 - ❑ Someone else who was named “Matt Bishop”

Disambiguating Identity

- ❑ Include ancillary information in names
 - Enough to identify principal uniquely
 - X.509v3 Distinguished Names do this
- ❑ Example: X.509v3 Distinguished Names
 - /O=University A/OU=Department of Computer Science/CN=David Smith/
refers to the David Smith (CN is *common name*) in the Department of Computer Science (OU is *organizational unit*) at University A (O is *organization*)

Certificate Authorities and Policies

- “David Smith” wants a certificate from Certs-from-Us
 - How does Certs-from-Us know this is “David Smith”?
 - CA’s *authentication policy* says what type and strength of authentication is needed to identify Matt Bishop to satisfy the CA that this is, in fact, David Smith
 - Will Certs-from-Us issue this “David Smith” a certificate once he is suitably authenticated?
 - CA’s *issuance policy* says to which principals the CA will issue certificates

Example: Vendor Defined Certificate Classes

- See <http://www.symantec.com/page.jsp?id=roots>

Internet Certification Hierarchy

□ Tree structured arrangement of CAs

- Root is [Internet Policy Registration Authority](#), or [IPRA](#)
 - Sets policies all subordinate CAs must follow
 - Certifies subordinate CAs (called *policy certification authorities*, or PCAs), each of which has own authentication, issuance policies
 - Does not issue certificates to individuals or organizations other than subordinate CAs
- PCAs issue certificates to ordinary CAs
 - Does not issue certificates to individuals or organizations other than subordinate CAs
- CAs issue certificates to organizations or individuals

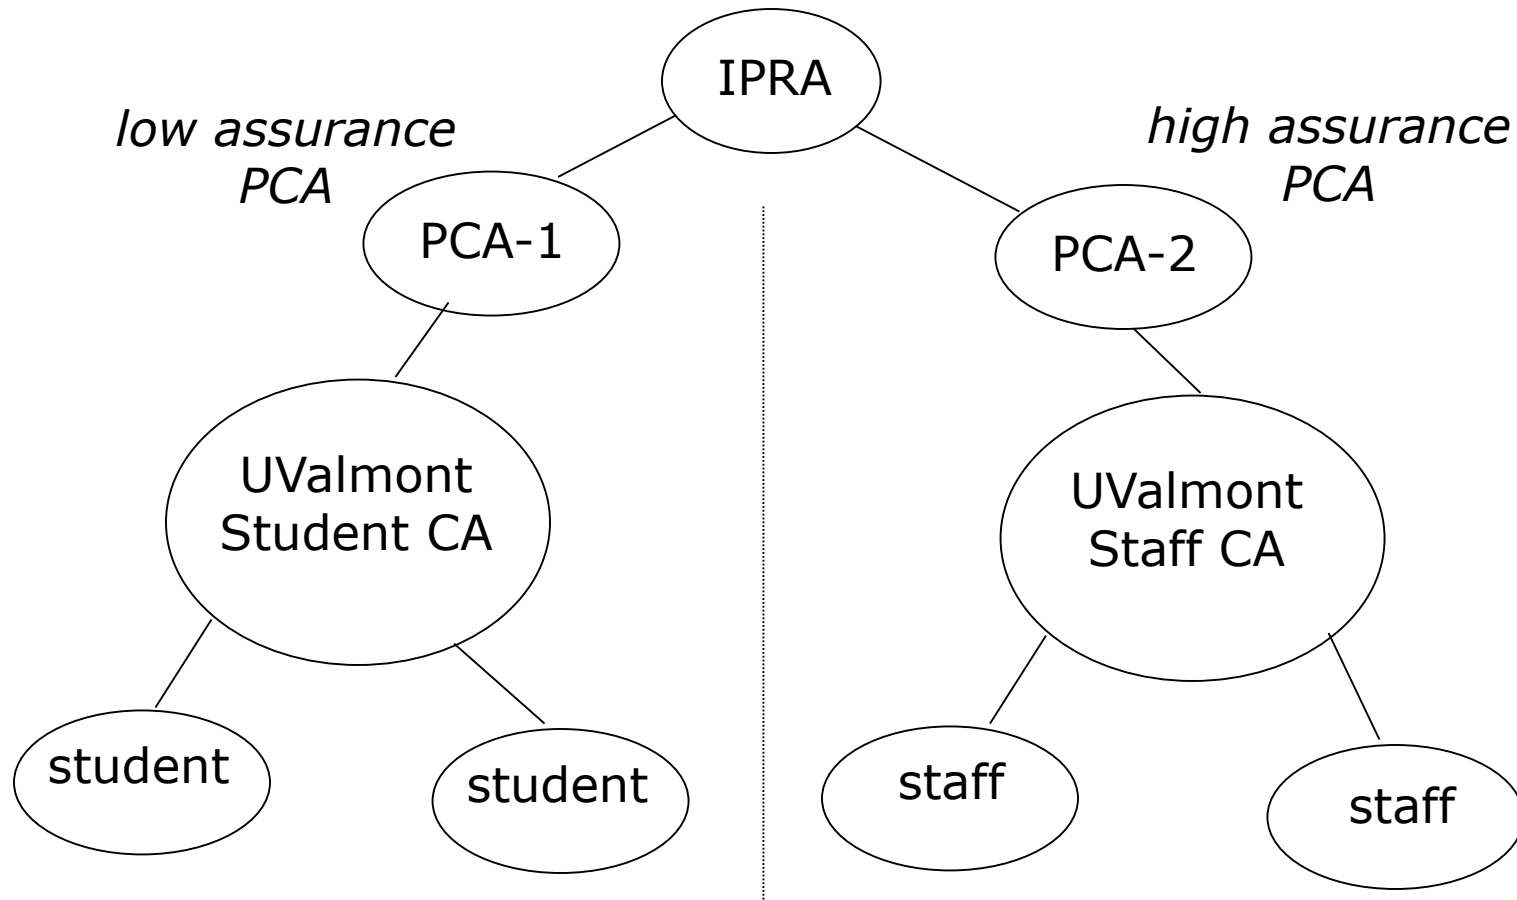

Example

- ❑ University of Valmont issues certificates to students, staff
 - Students must present valid registration cards (considered low assurance)
 - Staff must present proof of employment and fingerprints, which are compared to those taken when staff member hired (considered high assurance)

UValmont and PCAs

- ❑ First PCA: requires subordinate CAs to make good-faith effort to verify identities of principals to whom it issues certificates
 - Student authentication requirements meet this
- ❑ Second PCA: requires use of biometrics to verify identity
 - Student authentication requirements do not meet this
 - Staff authentication requirements do meet this
- ❑ UValmont establishes two CAs, one under each PCA above

UValmont and Certification Hierarchy

Certificate Differences

- ❑ Student, staff certificates signed using different private keys (for different CAs)
 - Student's signed by key corresponding to low assurance certificate signed by first PCA
 - Staff's signed by key corresponding to high assurance certificate signed by second PCA
- ❑ To see what policy used to authenticate:
 - Determine CA signing certificate, check its policy
 - Also go to PCA that signed CA's certificate
 - ❑ CAs are restricted by PCA's policy, but CA can restrict itself further

Types of Certificates

❑ Organizational certificate

- Issued based on principal's affiliation with organization
- Example Distinguished Name
/O=University of Valmont/OU=Computer Science
Department/CN=Marsha Merteuille/

❑ Residential certificate

- Issued based on where principal lives
- No affiliation with organization implied
- Example Distinguished Name
/C=US/SP=Louisiana/L=Valmont/PA=1 Express
Way/CN=Marsha Merteuille/

Certificates for Roles

- Certificate tied to a role

- Example

- UValmont wants comptroller to have a certificate

- This way, she can sign contracts and documents digitally

- Distinguished Name

- /O=University of Valmont/OU=Office of the Big Bucks/RN=Comptroller

- where “RN” is *role name*; note the individual using the certificate is not named, so no CN

Meaning of Identity

- ❑ Authentication validates identity
 - CA specifies type of authentication
 - If incorrect, CA may misidentify entity unintentionally
- ❑ Certificate binds *external* identity to crypto key and Distinguished Name
 - Need confidentiality, integrity, anonymity
 - ❑ Recipient knows same entity sent all messages, but *not* who that entity is

Persona Certificate

- ❑ Certificate with meaningless Distinguished Name
 - If DN is
/C=US/O=Microsoft Corp./CN=Bill Gates/
the real subject may not (or may) be Mr. Gates
 - Issued by CAs with persona policies under a PCA with policy that supports this
- ❑ PGP certificates can use any name, so provide this implicitly

Example: Whistleblower

- ❑ Government requires all citizens with gene Y to register
 - Anecdotal evidence people with this gene become criminals with probability 0.5.
 - Law to be made quietly, as no scientific evidence supports this, and government wants no civil rights fuss
- ❑ Government employee wants to alert media
 - Government will deny plan, change approach
 - Government employee will be fired, prosecuted
- ❑ Must notify media anonymously

Example: Whistleblower

- ❑ Employee gets persona certificate, sends copy of plan to media
 - Media knows message unchanged during transit, but not who sent it
 - Government denies plan, changes it
- ❑ Employee sends copy of new plan signed using same certificate
 - Media can tell it's from original whistleblower
 - Media cannot track back whom that whistleblower is

Trust

- ❑ Goal of certificate: bind correct identity to DN
- ❑ Question: what is degree of assurance?
- ❑ X.509v3, certificate hierarchy
 - Depends on policy of CA issuing certificate
 - Depends on how well CA follows that policy
 - Depends on how easy the required authentication can be spoofed
- ❑ Really, estimate based on the above factors

Example: Passport Required

- ❑ DN has name on passport, number and issuer of passport
- ❑ What are points of trust?
 - Passport not forged and name on it not altered
 - Passport issued to person named in passport
 - Person presenting passport is person to whom it was issued
 - CA has checked passport and individual using passport

PGP Certificates

- ❑ Level of trust in signature field
- ❑ Four levels
 - Generic (no trust assertions made)
 - Persona (no verification)
 - Casual (some verification)
 - Positive (substantial verification)
- ❑ What do these mean?
 - Meaning not given by OpenPGP standard
 - Signer determines what level to use
 - Casual to one signer may be positive to another

Summary

- ❑ Identity specifies a principal (unique entity)
 - Same principal may have many different identities
 - ❑ Function (role)
 - ❑ Associated principals (group)
 - ❑ Individual (user/host)
 - These may vary with view of principal
 - ❑ Different names at each network layer, for example
